

c) As the extinction rate slowly increases, species 1 becomes the first to become negative at equilibrium.

d) As the extinction rate increases, the equilibrium level of species two decreases.

7.4 a) Using Lotka-Volterra models we can view the natural extension of the logistic model to two species. But it may not account for other interactions that could result in an equilibrium between the two species.

b) When two species are grown together then we expect the outcome to be lower populations if competition occurs. This tends to be relatively easier in a lab setting.

c) According to Gause's competitive exclusion principle, in order to coexist, species must differ in their resource use. So looking and finding overlapping resources is important to accurately simulate competition in a lab setting.

d) Lotka-Volterra competition models are not adequate descriptions. Studies of competition models in the field show that competition does occur, but at times does not show the true force that regulates the population.

c) As the extinction rate slowly increases, species 1 becomes the first to become negative at equilibrium.
